Create Data Frame with Relative Weight and Gabelhouse Length Categories

Alex J. Benecke

December 19, 2017

Here I need to make two data files. Both need to cantain fish caught in the years 2012-2016 (even though I will only be using years 2014-2016). Both will contain the Relative Weight (Wr) of each fish and the gabel house length category each fish fits into. Then I will create two CLEAN data files one of wich will contain only fish larger than stock length and another with all fish of any length. The data file with fish of all lengths will be used to compare the length frequency distribution between years. The data frame with only gish stock length and larger will be used to compare the proportional size densities between years and with the relative weight between years.

```
Cond <- read.csv("./Data/Raw-Data/2012-2016_nearshore-survey_largemouth-bass.csv") %>%
  mutate(logW=log10(Weight),logL=log10(Length))
Cond$fyr <- factor(Cond$Year)

str(Cond)
```

```
## 'data.frame':    496 obs. of  13 variables:

```
#write.csv(Wr_fyr.gcat,file = "Data/Raw-Data/relative-weight_largemouth-bass_RAW.csv")
```

I have created a file with the relative weight of each gabelhouse length category for each year. The file name is relative-weight_largemouth-bass_RAW.csv.

Note

The relative weight data contains only stock length individuals. This is so that I can easily compare the relative

weight of fish with PSD. This is done despite the min TL being 150 mm. I may want to summarize relative weight for 150mm and greater length individuals in the future to see if young/small fish drive down or increase Wr.
